A non-linear equation from photopolymerization kinetics

ABSTRACT

In a medium where a photoreactive species produces N equally photoreactive radicals, by combining the Lambert-Beer law for the decay of light intensity, as a beam propagates into the medium, with the kinetic equation, one obtains a generalization of the Wegscheider equation from photobleaching theory. It is shown that this equation can be solved exactly, but implicitly, and can be reduced to a first order ordinary differential equation in a single reduced variable.

Introduction

As a light beam propagates into a medium containing a various photoreactive species the beam intensity decreases with depth due to absorption proportional to the concentration of the active molecules as is described by the Lambert-Beer law [1]. By combining this law with the kinetic equation one obtains a non-linear first order integro-partial differential equation. Situations where the N radicals released lead to desirable effects, such as bleaching and polymerization, have been studied for many years. An extensive list of references is presented in [2]. For the case of a single species the Lambert-Beer law for the light intensity

$$I(x,t) = I_0 \exp[-\alpha \int_0^x C(u,t)du]$$
 (1)

combined with the kinetic equation

$$\frac{\partial C(x,t)}{\partial t} = -\phi \alpha I(x,t)C(x,t) \tag{2}$$

gives Wegscheider's equation [3]

$$\frac{\partial C(x,t)}{\partial t} = -\phi \alpha I_0 \exp[-\alpha \int_0^x C(u,t) du] C(x,t)$$

$$C(x,0) = C_0. \tag{3}$$

whose solution has been known for many years [2]. Here C is the concentration, α is the absorption coefficient, and ϕ the quantum yield. For the case of a slab 0 < x < L, in terms of reduced variables $T = \phi \alpha t$, z = x/L, $S_0(z,T) = C(x,t)/C_0$, $\gamma = \alpha C_0 L$, the solution is

$$S_0(z.T) = [1 + e^{-\gamma z}(e^T - 1)]^{-1}$$
(4)

which is examined thoroughly in [2].

Systems are presently under investigation [4] where, not only the initial species, whose concentration is C, but its N reaction products all have the same absorption coefficient. A similar analysis leads to the more general equation, expressed in terms of the dimensionless variables given above,

$$\frac{\partial C(z,T)}{\partial T} = -e^{-N\gamma z} \exp\left[\gamma \int_0^z C(u,T)du\right] C(z,T)$$

$$C(z,0) = 1.$$
(5)

The aim of this note is to present the exact, albeit implicit, solution to (5).

Calculation

We first introduce the cumulative concentration $\sigma(z,T)=\int_0^z S(u,T)du$ for which $\sigma(z,0)=z$ and $\sigma(0,T)=0$. Then by integrating both sides of (5) over z and then differentiating with respect to z, one finds

$$\frac{\partial^2}{\partial z \partial T} [\sigma(z,T) - Nz] = -e^{-\gamma [\sigma(z,T) - Nz]} \frac{\partial}{\partial z} [\sigma(z,T) - Nz]. \tag{6}$$

That is, for $f(z,T) = \sigma(z,T) - Nz$ one has the partial differential equation

$$\frac{\partial^2 f(z,T)}{\partial z \partial T} + \left(\frac{\partial f}{\partial z} + N\right) e^{\gamma f(z,T)} = 0 \tag{7}$$

with f(z,0) = -(N-1)z, f(0,T) = 0. Next, we introduce $V(x,T) = -\log[f_z + N]$ to obtain

$$\frac{\partial^2 V(z,T)}{\partial z \partial T} = -\gamma \frac{\partial}{\partial t} (e^{-V(z,T)} + NV) \tag{8}$$

which, after integration with respect to T becomes

$$\frac{\partial V(z,T)}{\partial z} = \gamma (1 - NV - e^{-V})$$

$$V(0,T) = T.$$
(9)

From (9) we get the implicit relation

$$\int_{T}^{V(z,T)} \frac{ds}{1 - Ns - e^{-s}} - \gamma z = 0 \tag{10}$$

or, since $S = e^{-V}$, following a simple change of integration variable,

$$\int_{S(z,T)}^{e^{-T}} \frac{du}{u(1+N\log u - u)} - \gamma z = 0.$$
 (11)

Finally, in terms of the new variables

$$\tau = \int_{\ln 2}^{T} \frac{du}{1 - Nu - e^{-u}}$$

$$\xi = \gamma z - \tau$$

$$S(z, T) = S(\xi),$$
(12)

we find that the solution to (5) has the implicit representation

$$\int_{1/2}^{S(\xi)} \frac{du}{u(1+N\ln u - u)} = \xi. \tag{13}$$

Discussion

Let us first look at the case N=0, which renders (5) equivalent (under $S=-S_0$) (mathematically, but not physically) to the Wegscheider equation [1]. By explicit integration $\tau=\ln(e^T-1)$, $S(\xi)=e^\xi(e^\xi+1)^{-1}$ and we recover the solution (4). Note that (13) is equivalent to the first order ordinary differential equation

$$S'(\xi) = \xi(1 + N \ln \xi - \xi)$$
 (14)

subject to an appropriate initial condition. Eq. (14) should be useful for obtaining series approximations to S(z,T). It also indicates that for N>0 S(z,T) is nonanalytic along the trajectory $\gamma z=\tau$.
